Thesis Draft

Tidal Patterns in Small Coastal Lagoons

Mira Okafor

Department of Marine Studies, Lakemoor Institute

Working draft for supervisor review

Chapter One: Introduction

Small lagoons along sheltered coasts fill and drain with every tide, yet the timing of that exchange is rarely measured in detail. This chapter describes a simple method for logging water level with low cost sensors, and compares the readings with tide tables for the nearest harbour.

The results suggest that narrow inlets delay the peak level inside the lagoon by a predictable amount, which matters for anyone planning field work, boat access or habitat surveys at the water edge.

Small lagoons along sheltered coasts fill and drain with every tide, yet the timing of that exchange is rarely measured in detail. This chapter describes a simple method for logging water level with low cost sensors, and compares the readings with tide tables for the nearest harbour.

Chapter Two: Measurements

The results suggest that narrow inlets delay the peak level inside the lagoon by a predictable amount, which matters for anyone planning field work, boat access or habitat surveys at the water edge.
